

## **Introduction**

Continuous Integration (CI) is a software development practice where members of a team integrate their work frequently. Modern CI-tools generate a bulk of data with each commit. One of the main problems is that relevant information about the quality and health of a software system is both scattered across those stand-alone CI tools and across multiple views. Therefore stakeholders need more time to come up with answers for the questions regarding the software quality and still there is lack in accuracy in the answers.

We address this problem by concerning the quality aspects of the Software and customize this information to all kind of stakeholders, such as developers, project managers, testers etc. For that we present a quality awareness pipelined integration framework which includes service combination techniques, integration of information from the entire CI-toolchain and giving customizable or dynamic view using pipelining techniques

## **Background and Motivation**

How easy for different stakeholders for answering questions about software quality in different perspective with integrated pipelined CI-tools compared to the use of available standalone CI-tools? The integration of modern CI-tools within the development process of a software project is fully automated, and its execution is triggered after every commit. Developers or testers perceive the CI process most often only in case of a build break or test failure. In such a case, they get an automatically generated notification that is via email. Developers can then fix the problem using this information. This kind of exception-driven behavior helps to detect and fix problems as early as possible during integration runs.

Modern CI-tools can generate a bulk of data with each commit, Before the build or test failures,. This data is available across the entire CI-toolchain and analyzing it, for instance, to monitor quality of a system is a time consuming task. This can delay the rapid feedback cycles of CI and one of its major benefits is then not realized.

Software quality is hard to find with the stand alone CI tools. Let's find the change between two builds and who has changed it? Answering these kinds of questions require two steps. First, we need to know the dates of the respective builds. Then, these build dates can then be used to answer the question itself by investigating, For examples Commit logs, file-diff data, build details, issue details etc. However, to obtain the relevant information a developer must access several different tools and navigate through multiple views.

We implement a pipelined integration framework for combining data from various tools. We allow every stakeholder to customize the view according to their need. Here views are created based on the pipes, the stakeholder use. Every pipe includes a quality measurement from various CI tools. We also provide a default overview on the software quality which includes a set of often needed quality information on the source code. The default overview will be generated based on the composition of the quality measurements by using our newly developed algorithm.

## Problem in Brief

Even Though the most of the quality information on software are available across the various CI stand-alone tools, there is much time and effort needed to monitor the most relevant quality of the software out of that scattered quality information. There is also an issue on the accuracy of the information gathered from a CI tool.

## Aim

The aim of our approach is to integrate the information scattered across the CI-tooling landscape into a single web based service and to present it according to the information needs of different stakeholders. Our approach will provide a fast and accurate way to evaluate the software quality.

## Objectives

- Learn the software quality metrics and implement it as a service.
- Study the web service composition and develop new algorithm.
- Study the pipeline technologies and implement.
- Study about the API and composition.
- Study about web services.
- Study about various CI tools and their functions.

## Our Proposed Solution

As described in the figure 01 we use the Application Programming Interface (API) to gather data from the CI tools, we also implement a new module and take the information from the API. We process the data and transfer to a common data format. In the pipeline integration we bind the data to pipes. The stakeholders can drag and drop the pipes so that they can tailor their needed information. In the data extraction process we will use a composition algorithm to generate the information needed to generate the default view of any stakeholders.

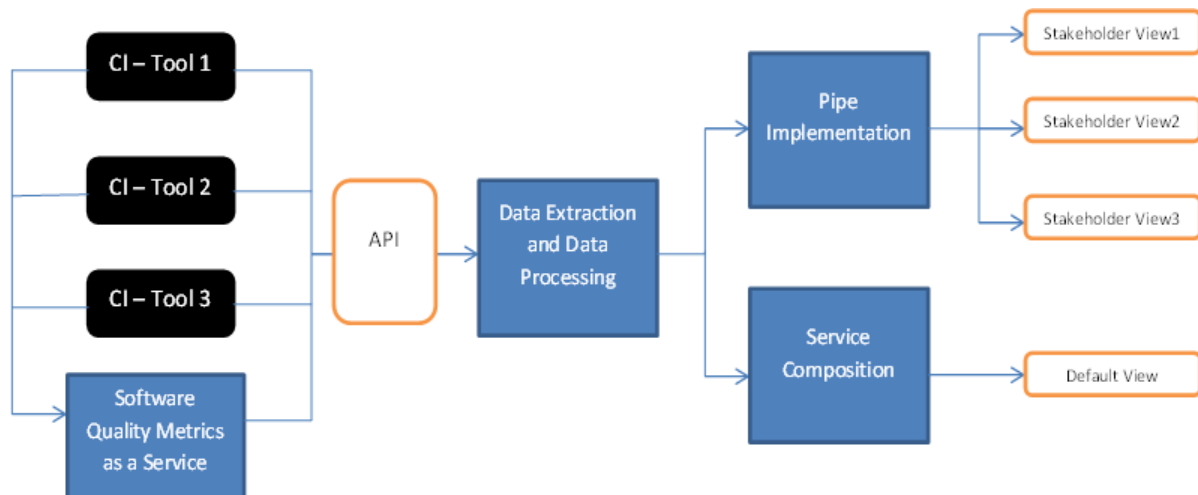

Figure 01

Here we address this problem using different technologies. The solution consists of four major modules.

### **1. Data Extraction and Processing**

Quality information will be gathered from various CI tools via Application Programming Interfaces. This is a bit challenging part as CI tools will provide data in different formats. We need to gather information from the CI tools and process them, so that we can come up with the common data format to make easy the data processing.

### **2. Software Quality Metrics as a Service**

Certain quality information about the software will be required to evaluate a particular software quality. The above mentioned CI tools have provided some of the often used quality measurements. There are some quality measurements not available in those CI tools, Therefore we need to add them to evaluate the software quality.

There are number of software quality metrics which are introduced by various researches. They are not yet implemented, we are planning to implement those software metrics and use its quality information in our data extraction process. We implement those software quality metrics as a service so that any third party can consume.

### **3. Pipe Implementation**

We hope to use the pipeline implementation to make the job easy. Quality information from various CI tools is bound to pipes. Piping technology allows a set of pipes to combine in a way so that the bound data in the pipes can deliver useful information. Piping technology provides combining any number of pipes. We use this feature to allow stakeholders to customize according to their information needs to the software quality.

### **4. Quality Information Service Composition**

There are certain quality measures stakeholders often need. We planned to provide those quality measures in a default view. Here we use different services from the CI tools and use a better service composition to determine the software quality. We will create our own composition algorithm for the above purpose.

### **Resource Requirements**

Before a project can be authorized it is vital that a corporation consider the resources needed to support it. Resources include needed personnel, equipment, facilities, processes, and funding. Should insufficient resources be available it may be necessary to either outsource portions of the project, or reduce its scope to fall within available resources. The below points describe the required resources for this system to run.

### **Hardware Requirements**

- 40 GB or more hard disk space
- 1 GB or more RAM
- Minimum 2 GB swap area (Linux)
- 2.0 GHz minimum processing power
- Setting limits with ulimit to 50000 (Linux)

### **Software Requirements**

- Eclipse
- Enterprise Service Bus
- MySQL Community Server
- GitHub
- SonarQube
- Jenkins
- Jersey Framework

### **Platform Requirements**

- OS - Windows / Linux
- Apache tomcat
- Java Development Kit
- OSGi Service Platform
